

Aerial Spray Plume Dispersion Measured With Lidar

David Miller, University of Connecticut

April Hiscox, University of Connecticut

James Ross, New Mexico State University

Carmen Nappo, NOAA, ATTD

Project Objectives

- Quantify Aerial Spray Plume Characteristics and Dynamics for:
 - Small size distribution sprays – Vector control
 - Calm Stable Conditions

Spray Application

- Aircraft: Cessna T188C
- Atomizers: Micronaire AU5000 rotary atomizers
- Spray solution: water with 9% vegetable oil and 1% adjuvant
- $DV_{0.1} = 13.3\mu$, $VMD = 37.3\mu$, $DV_{0.9} = 82.8\mu$
- Application rate: 21.6 gallons / acre

3-D Sonic Anemometer

Meteorological Conditions at the Spray Height During Single Spray Passes

•	Pass 1	Pass 2	Pass 3	Pass 4	Pass 5
• Time	6:17:47	6:24:51	6:50:54	6:56:59	7:04:09
• U (m/s)	1.44	0.83	1.99	1.63	2.21
• Udir (deg)	32	46	71	60	58
• ζ (stability)	126.5	36.0	20.5	185.8	-28.5
• T (C)	8.5	8.9	9.2	9.4	9.7
• RH (%)	74	74	57	52	49

Slice Through Plume 3 seconds after Spray Release

Plume Cross Section and Location after 2.5 Minutes

Plume Cross Section and Location after 5 Minutes

Finding σ_s

$$\frac{\chi_e}{\chi_m} = e^{-\frac{z_e^2}{2\sigma_z^2}}$$

$$\alpha = \frac{B_M}{B_c}$$

$$\sigma_i^2 = \frac{\left(\frac{\Delta z}{2}\right)^2}{-2 \ln \alpha}$$

B_c = backscatter value at plume edge

Plume Dispersion, Stable Conditions

Plume Dispersion, Unstable Conditions

Conclusions

- Applications of very small droplets resulted in drifting plumes, which dispersed very slowly in stable air.
- About 40% of the active ingredient and 10% of the total mass sprayed remained air borne.
- During stable conditions the plume spread for 1-2 minutes and then stopped spreading. The initial spread was due to the turbulence caused by the aircraft.
- During unstable conditions, the plumes continued spreading indefinitely due to atmospheric turbulence.
